

659.11

Introduction

FMRI has been used to demonstrate awareness and communication in patients who are clinically in the vegetative state (VS) and low-level minimally conscious state (MCS).^{1,2}

There are obvious practical limitations to the development of a fMRI communication tool for severely brain injured patients.

EEG testing at the bedside has several advantages. It is inexpensive, allows study of patients who cannot travel, and allows repeated testing of patients in different states of arousal.

Quantitative EEG analysis, specifically calculation of power spectra, can be used to index changes in brain activity.

We demonstrate here EEG power spectral changes in healthy controls and patient subjects asked to perform a motor imagery task. Patient subjects chosen all showed significant BOLD changes on a related fMRI task (see 659.7).
